# Bayesian probability modeling 

James T. Pełerson
USGS Oregon Cooperalive Fish and Wildlife Research Unit Homepage: http://people.oregonstate.edu/~peterjam/

## First, some definitions...

## Certainty: An event is considered certain if it is $100 \%$ likely to happen

Uncertainty: Anything that falls short of absolute certainty

Uncertainty generally incorporated into natural resource decision modeling using probability

Common forms of uncertainty in natural resources management decision making

## Linguistic

Episłemic
Statistical uncertainty Observational error Structural uncertainty

Aleatory
Environmental variability
Reducible

Demographic variability

## Often overlooked source of uncertainty

## Structural (System) uncertainty

due to incomplete understanding of system dynamics

Incorporated into decision modeling using multiple models and model probabilities (weights)

## Bayesian inference

## Bayesian example

Imprecise prior
Precise prior

# Influence of prior and sample data on posterior 

## Precision

Prior $\S$, data $凸$, posterior $\rightarrow$ prior
Prior $凸$, data $\}$ posterior $\rightarrow$ sample

## Sample size

> samples, greater influence

## Where do we get priors?

## Meta analysis

 previous studies published reports
## Expert elicitation

## Diffuse (non-informative)

## Commonly used fools

# Monte Carlo Markov Chain (MCMC) <br> Integrate multiple data types, sources, and models <br> Natural fit 

## Probabilistic networks

Bayesian belief networks Influence diagrams

## Example: Southeast resource assessment

Evaluation of potential climate change effects stream flows temperature

All habitat and fish population data from southern portion of ACF basin

Very sparse data available for adjacent basins in Blue Ridge

Iask: develop models for response of cool water biota

Apalachicola, Chattahoochee, Flint Basin

## Existing models of flow-fish relation (the prior)

Traił based

Flow variability during spawning and rearing

## Existing models of flow-fish relations (the posterior)

## So.. how is this useful for water resource decision-making?

Assuming that we have
Objectives Decision alternatives

## Modeling decisions

Existing models/components

Meta-analysis
"Expert" judgment
Data(?)

# Common question: <br> Won't the priors affect the model estimates and decision making? 

## Maybe/probably/yes , but .....

## Sensitivity analysis

## Identify key uncertainties sensitivity analysis

Identify the uncertainties affect decisions What would we do dififerently if we knew X?

## Prioritize research and monitoring

Focus on decision-making What do we need to know?
How much is enough?

# Example: Wafer availabilify for ecological needs in the ACF Basin 

## Spatially explicit

Stream segment
Flow, habitat, fish metapopulation models (43 species)

## Statistical uncertainty

flow and habifat model errors

## Structural (system) uncertainty

Alternative fish population demographics models

## What assumptions/inputs affecł the decision?

## Reducing Uncertainty

## New studies / Experiments

## Adaptive management (monitoring)

## Reducing uncertainty

Often want to know... What will it gain?
How much is needed? How much is enough?

## Value of information

Expected value of decision if no uncertainty
Model parameters
Model inputs and system state
Currency that is valued by the decision-makers
Fish population size
Water available for use
Others

## Value of perfect information

## Example: Alternative extinction hypotheses

Assume constraint: species loss < 5\%

| System dynamics | Daily water <br> withdrawal <br> (MGD) |
| :---: | :---: |
| Chronic flows | 3.50 |
| Acute low flows | 1.37 |
| Weighted average | 2.44 |

## Composite estimate

 1.83 MGDValue of perfect information: 2.44-1.83 = 0.61 MGD

## Value of information

## But... not all information is perfect (it almost never is)

Some sources of imperfection
Sampling error
Incomplete understanding of process
Random error
Others???

## Value of imperfect information

## Value of sample information

Multi-species occupancy simulations
2 sample occasions, error (CV) ~ 35\%
True richness, given estimated 25: 25 +/- 4
Value of sample information: 0.26 MGD
4 sample occasions, error (CV) ~ 10\%
True richness, given estimated 25: 25+/-2
Value of sample information: 0.49 MGD

Compare to EVPI = 0.61

## Reducing uncertainty: monitoring

## Spring and summer 2011-2012 (2013) 21 sites, 40-100 m

## Electrofishing and seining

Occupancy 2-3 visits season
Flint River Basin

## Update model probabilities

Peterson and Freeman

# Updated estimates of water use effects 

## Summary

Bayesian approaches<br>Underutilized<br>Cost/effort savings<br>Leverage existing information<br>Propagate uncertainty<br>Learning through time/space (reduce uncertainty)

## Natural fit with decision modeling

Identify important uncertainties
Value of (im)perfect information
